# Other types of Chemical Signaling

In endocrine signaling, hormones, secreted into extracellular fluid diffuse into blood or lymph & then travel a greater distance throughout the body.

An autocrine signaling takes place within the same cell

e.g. Interleukin-1 IL-1 is a signaling molecule that plays an important role for inflammatory response.

The cells themselves have receptors in their membrane/surface that bind to these molecules, resulting in autocrine signaling.

Paracrine aka Paracrine factor

↳ conducts local intracellular communication including response to neighboring cells

Asthma → histamine → a paracrine that is released by immune cells in the bronchial tree

H. causes the smooth muscle cells of the bronchi to constrict, narrowing the airways
