AP-17-25 10.11.2026

cAMP → cyclic adenosine monophosphate

converts ATP to cAMP

The 2nd cAMP (cyclic adenosine monophosphate) activates a 2nd type of enzyme called a protein kinase (present in the cytosol)

* Activated protein kinases init a phosphorylation cascade → in which multiple protein kinases phosphorylate (+ a phosphate group)

↳ to numerous & various cellular proteins (& other enzymes)

The phosphorylation of cellular proteins can trigger a wide variety of effects, from nutrient metabolism to the synthesis of diff hormones. Effects may vary →

Ex of Hormones that use cAMP as a 2nd mssgr include calcitonin

for bone construction / blood cal levels

glucagon → plays a role in blood glucose levels
