AP 18.2-10 10.12.2026

Sites of Hemopoiesis

prior to birth hemopoiesis occurs in a number of tissues → begins with the yolk sac of the developing embryo & continuing in the fetal liver, spleen, ~~lins~~ lymphatic tissue & eventually → bone marrow (red)

Following birth → most hemopoiesis occurs in red bone marrow, a connective tissue within the space of spongy (cancellous) bone tissue.

In children → Hemopoiesis can occur in the medullary cavity of the long bones while in adults → the process is largely restricted to the cranial & pelvic bones ← Really?

along with the cranial & pelvic, bones, the vertebrae, the sternum & proximal epiphyses of the femur & humerus

Throughout adulthood → the liver & spleen maintain their ability to generate the formed elements.

> process is refered > means → outside of the medullary cavity of adult bones

Extramedullary Hemopoiesis
