A disease such as bone cancer → destroys the bone marrow, causing hemopoiesis to fail → while extramedullary hemopoiesis may be initiated.

~~Differentiation~~ Differentiation of ~~Elements~~ Formed Elements from Stem cells

Bone marrow → all formed elements arise from stem cells of the red bone marrow.

Stem cells go under mitosis plus cytokinesis (cell division) to give rise to ~~a~~ new daughter cells. One remains a stem cell → the other diffs into one of many/other cell types.

Stem cells - hierarchy → each step in diff losses its pluripotentancy

① Totipotent → zygote (fertilized egg) all gives rise to all cells in the human body (the cosmic ⊜ Class)

② Pluripotent → gives rise to multiple types of cells depending on markers → some supporting fetal membranes

Subpluripotent would be mesenchymal cell

That develops into connective tissue

fibrous - connective bone, cartilage, blood

NOT epithelium, muscle nervous tissue
