(3) finally → Hematopoietic cell or hemocytoblast

Hemopoiesis begins when the Hematopoietic stem cell is exposed to appropriate chemical stimuli → collectively called

→ Hemopoietic growth factors

prompts the cell to divide & diff

1 daughter cell remains a hematopoietic stem cell → which allows hemopoiesis to continue

The other daughter cells becomes either of two types or more specialized stem cells

• Lymphoid stem cells → gives rise to a class of leukocytes known as lymphocytes

→ which include the various T-Cells, B-cells, & natural killer cells (NK)

★ Remember this → all these function in immunity

→ Hemopoiesis of lymphocytes progresses somewhat differently from the process of other formed elements → how so? → ~~lymph nodes~~

Lymphoid stem cells quickly migrate from bone-marrow
