Cytokines → glycoproteins secreted by a wide ~~variat~~ variety of cells, including red bone marrow, leukocytes, macrophages, fibroblasts → & endothelial cells.

They act locally as autocrine (self) or paracrine (neighbor cells) factors, stimulating the ~~prof~~ prolife cation → of progenitor cells & helping to stimulate both nonspecific & specific resistance to disease.

Colony-Stimulating factors

are glycoproteins → that act locally, as autocrine or paracrine factors → some tigger the diff of myeloblasts into granular leukocytes

which are referred to as granulocyte CSFs
