Neutrophils → are the most common type of leukocytes → compose 5ϕ-7ϕ % of total leukocyte count.

↳ they are 1ϕ-12 μm diameter, significantly larger than RBC

Called Neutrophils → Because their granules show up most clearly with stains
↳ chemically neutral / not acidic or basic

may have two - 5 lobes → older ~~netrop~~ neutrophils have more lobes →
This is refered to polymorphonuclear
↳ nucleus with many forms → Greek - poly

younger neutrophils → begin to develop "bands"

Neutrophils - are rapid responders to the site of infection & are efficient phagocytes with preference for bacteria { granules - include lysozyme

lysing breaks cell walls + H_3O

& defi defensins → proteins that bind / puncture cell walls - fungal plasma membranes - cells - content leaks out

high neutrophil count → infection → inflammation
burn patients

Eosinophils typically → 2-4 % of total leukocyte count

are also 1ϕ-12 μm in diameter.

The granules → of Eosinophils stain best with Acidic stain known as eosin
