AP-18.4-35 10.13.26

The size of Range of lymphocytes → quite extensive →
with some authorities → recognize two size classes
some say there is 3
They are typically large cells are 10-14 μm & have a smaller nucleus-to-cytoplasm ratio & more granules → Smaller cells -
→ typically 6-9 μm → larger nucleus to-cytoplas →
↳ they create a halo effect.
The cells that fall out of this range → are 14-17 μm

3 major classifications of lymphocytes → include natural killer cells, B cells, T-cells

NK- Natural Killer cells → are capable of recognizing cells that do not express "self" proteins on their plasma membrane or that contain foreign or abnormal markers

"noneself" cells → include cancer cells → infected cells with a typical surface

They provide generalized → none-specific immunity

Larger ~~T&B~~ Lymphocytes are typically NK cells

B cells & T-cells → also called (B lymphocytes → & T-)

play a role in defending the body against specific pathogens (disease causing microorganism)

B-cells are Specific immunity
