# Formation of the Platelet Plug

In the 2nd step → platelets → which normally float free in the plasma → -normally float free in the plasma, encounter the area of vessel rupture with the exposed underlying connective tissue & collagenous fibers

→ Platelets begin to clump together → become spiked & sticky → & bind & endothelial lining

→ The process is assisted by glxco protein in

In the blood plasma called von Willebrand factor → helps stabilize the growing platelet plug. As platels collect they simultaneously release chemicals from their granules → into the plasma that contribute to hemostasis

Among the substances → released by the platelets are 2, ~~ATP~~ ADP → helps additional platelets ~~as to~~ 2) adhere to the injury site → ~~the~~ 2) reinforcing & expanding the platelet plug.

- serotonin which maintains vasoconstriction
- prostaglandins & phospholipids, which also maintains vasoconsecriction
