back to the pulmary → circulation

The right ventricle pumps deoxO2 blood into the pulmonary trunk ← ✱ which leads to the pulmary arteries

Pulmonary arteries - branch many times → reach Pulmonary capillaries where gas exchange occurs

CO2 exits the blood & O2 enters. The Pulmonary trunk arteries & their ~~ba~~ branches are the only arteries in the post-natal body that carries relatively ~~low~~ deOx O2

highly O2 blood from pulmonary capillaries in lungs passes through highly O2 blood → that join & form pulmonary veins

The pulmonary veins → is the only post-~~natal~~ natal veins in the body that carry highly O2 blood.

The P. Veins → conduct blood into the left atrium which pumps the blood into the left ventricle, which pumps O2 blood into the aorta & the many branches of the systemic circuit which lead to systemic capillaries

→ The capillaries will ultimately unite to form venules ← joining from even larger veins → which then flows into the two ~~mj~~ major systemic veins → i.e. The superior vena cava & inferior Vena ~~Ca~~ cava

✱ lower in O2
