AP 17.1 (10)

10. 15. 29
26

The endocardium (inner) is connected to the Myocardium by a layer of connective tissue.

The endocardium lines the chambers where blood circulates → & covers the heart valves

{ simple squamous epithelium) endothelium
→ which is continous with endothelial lining of blood vessel.

Recent evidence indicates - that the endothelium of the endocardium & the coronary capilaries may play active roles in regulating the contraction of muscle within the myocardium. The endothelium may also regulate the growth patterns of the cardiac muscle cells throughout life.

The endothelins it secretes - create an environment in the surrounding tissue that regulates ionic concentrations & states of contractility.

Endothelins → are potent vasoconstrictors - & in normal individual → establish a homeostatic balance with other vasoconstrictors & vasodilators

Internal Structure of the Heart

dual pattern of pulmonary & systemic

Because of the heart's contraction cycle follows the dual pattern of circulation

A more precise understanding of cardiac function →

Septa of the Heart

septum → something that closes → latin
