which are also covered by endocardium, this is known moderator band.

The moderator band reinforces the thin wall of the right ventricle & plays a crucial role in cardiac conduction.

It arises from the inferior portion of the interventricular septum & crosses the interior space of the right ventricle to connect with the inferior papillary muscle.

→ when the right ventricle contracts → it ejects blood into the pulmonary trunk which branches into the left & right pulmonary arteries that carry each it to each lung.

At the base of the pulmonary trunk is the pulmonary semilunar valve that prevents backflow from the pulmonary trunk.

Left Atrium → After exchange of gases in the pulmonary capillaries blood returns to the left atrium high in O_2 via one of the 4 pulmonary veins

The left atrium does not contain pectinate muscles, it does have an auricle that includes these pectinate ridges →

Blood flows nearly continuous from the pulmonary veins back to into the atrium, which acts as the receiving chamber & from here → through an opening into the, through an opening into the left ventricle

Blood passes passive when both atria & ventricles are relaxed
