AP (19.1)(16) Ch. 15: 25 26

→ but toward the end of the ventricular relation relaxation period, the left atrium will contract, pumping blood into the ventricle. This atrial contraction accounts for approx 20 percent of ventricular.

The opening between the left atrium & ventricle is guarded by the mitral valve

Left Ventricle

→ Recall → although both sides of the heart will pump the same amount of blood, the muscular layer is much thicker in the left ventricle compared to the right

just as the right Ventricle has a trabeculae carneae so does the left ventricle

No monitor band - thicker walls for LV

The mitral valve is connected to papillary muscles via chordae tendon

There are two papillary muscles on the left -- the anterior/posterior as opposed to 3 on the right.

The left ventricle is the major pumping chamber for the systemic circuit → it injects blood into the aorta through the aortic → semilunar valve

Heart Valve Structure & Function

→ The valves ensure unidirectional blood flow → Between the right atrioventricular valve → or tricuspid valve → typically consists of 3 flaps made of endocardium → + additional connective tissue
