* Important → Blood flow from Left Atrium to the left Ventricle

When two atrioventricular values are open
The two ~~sem~~ semilunar values are closed
~~The atria & vessels have been removed~~

* When the mitral value is open - it allows blood to move from the left atrium to the left ventricle

The aortic semilunar value is closed to prevent → backflow of blood from the aorta → to the left ventricle.

The atrioventricular values are ~~close~~ closed while the two semilunar values are open. This occurs when the ventricles contract to eject blood into the pulmonary trunk & aorta.

[Closure of the two atrioventricular values prevents blood being forced back to the atria]
