Unlike the atrioventricular valves, there are no papillary muscle or chordae tendineae associated with the pulmonary valve.

Located at the opening between the left atrium & left ventrical is the mitral valve → also called the Bicuspid Valve or the left artrioventricular valve. Structurely the valve consists of two cusps, compared to the 3 cusps of the tricuspid valve. ~~the mitral valve~~ The mitral valve is bicuspid The two cusps → of the mitral valve are attached by chordae tendineae to two pupillary muscles. that project from the wall of the ventricle

(At the base of the Aorta is the aortic semilunar valve, or the aortic valve
↳ this prevents the backflow from the aorta - (consists of 3 flaps)
when the ventricle
↳ relaxes & blood attempts to flow back into the ventricle from the aorta, blood will fill the cusps of the valve, causing it to close & producing an audible sound

The 2 atrioventricular Valves are open & two semilunar valves are closed
↳ which occurs when both atria & ventricles are relaxed & when the atria contract to pump blood into the ventricles

when this occurs → the pulmonary valve & Aortic valve } close
