AP (19.1 - 21) 16.16. 2φ 26

Why is the presence of chordae tendineae more critical for the antriventricular valves, i.e. the tricuspid & mitral than the semilunar (aortic - pulmonary valves)?

* Because perhaps pressure, & back flow of blood?

valvular heart disease

can range from non-life threatening to life threatening & lethal

some are congenital → trauma caused.

Valvular disorders → such as caused by carditis or inflammation of the heart. Scarlet fever aka rheumatic fever → response to bacterium

Streptococcus pyogenes → disease of childhood

the pulmonary & semilunar valves → are less frequent insufficiency depends on → which value.

Prolapsed Valve → If one of the cusps of the valve is forced backward by the force of the blood → chordea tendineae are damaged or broken → closure mech fail.

Blood is regurgitated → produced a heart murmur sound.

Stenosis → is a condition → heart valves calcify

eventual weakness of heart

Aortic Stenosis → affects approx 2% in individuals over 65, 4% of 85

Auscultation - listening to a patients heart

most useful tools → from Latin → "to listen"
