AP 19.1 (23) 1p. 1 & 2 of 26

The left coronary artery distribs blood to the left side of the heart, the left atrium & ventricle & the interventricular septum

The circumflex ~~artery~~ artery → arises from the left coronary artery & follows the coronary sulcus to the left. Eventually it fuses with small branch arising from the ~~left~~ coronary artery (Right)

The large Anterior

Interventricular Artery → aka the left anterior descending artery (LAD) is the 2nd major branch arising from the left coronary artery. ~~It~~ It follows the anterior interventricular sulcus around the pulmonary trunk.

Along the way it gives rise to numerous smaller branches that interconnect with the branches of the posterior ~~int-~~ ~~interventi~~ interventricular artery, forming anastomoses

↳ What is anastomoses? is an area where vessels unite to form interconnects that normally allow blood to circulate to a region even there may be blockage in another branch.

Anastomoses → in the heart ~~heart~~ are very small. Therefore, this ability is somewhat restricted in the heart, so a coronary artery blockage often results in death of cells (Myocardial infraction) → supplied by a particular vessel.

The right coronary artery proceeds along the coronary sulcus & distributes blood to the right atrium, portions of both ventricles → & the heart conduction system.

The marginal arteries supply blood to the superficial portions of the right ventricle

The posterior interventricular artery aka the posterior descending artery → runs along the posterior portion of the interventricular sulcus toward the APEX of the heart
