AP (19.2) (31)

The SA node ~~has the~~ initiates the sinus rythm → or normal electrical pattern followed by contraction of the heart.

This impulse spreads from its initiation in the SA node throught the atria through specialized

→ Intermodal Pathways → to the atrial myocardial contractile cells & atrioventricular node

Intermodal Pathway

The impulse takes approximately 50 ms to travel between these two nodes.

The relative importance of this pathway has been debated since the impulse would reach the antrioventricular → node simplify y following the cell-by-cell pathway → through the contractile

Interatrial Band → That conducts the impulse directly from the ~~right~~ right atrium to the left atrium.

Regardless of the pathway, as the impulse reaches the antrioventricular septum, the connective tissue of the cardiac skeleton prevents the impulse from spreading into the myocardial cells in the ventricles except at at the [atrioventricular node]
